Biased random-key genetic algorithms with applications to optimization problems in telecommunications

Invited talk given at U. Federal Fluminense Niterói, RJ, Brazil ❖ September 2011

Mauricio G. C. Resende AT&T Labs Research Florham Park, New Jersey

mgcr@research.att.com

## Summary

- Biased random-key genetic algorithms
- Applications in telecommunications
  - Routing in IP networks
  - Design of survivable IP networks with composite links
  - Redundant server location for content distribution
  - Regenerator location
  - Routing & wavelength assignment in optical networks
- Concluding remarks

# Biased random-key genetic algorithms

Holland (1975)

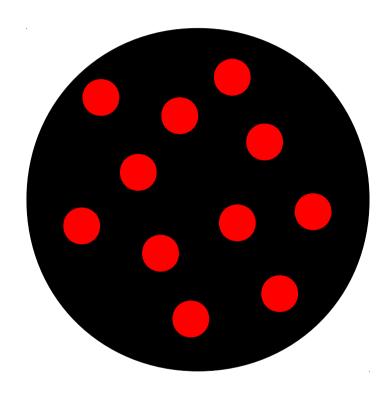

Adaptive methods that are used to solve search and optimization problems.

Individual: solution

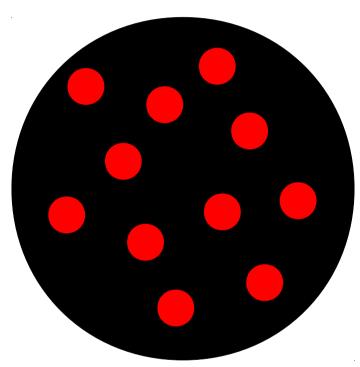

Individual: solution

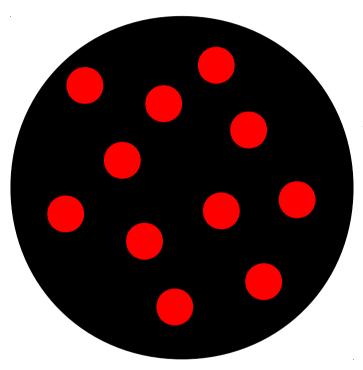

Population: set of fixed number of individuals

Genetic algorithms evolve population applying the principle of survival of the fittest.

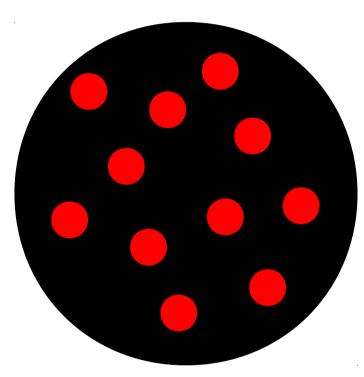

Genetic algorithms evolve population applying the principle of survival of the fittest.

A series of generations are produced by the algorithm. The most fit individual of last generation is the solution.

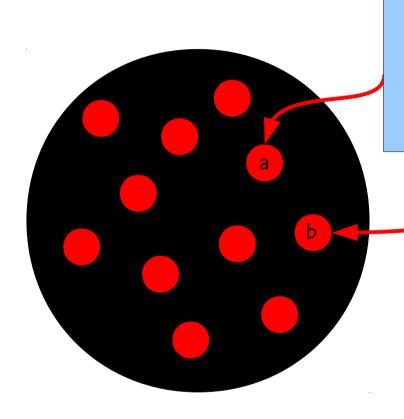

Genetic algorithms evolve population applying the principle of survival of the fittest.

A series of generations are produced by the algorithm. The most fit individual of last generation is the solution.

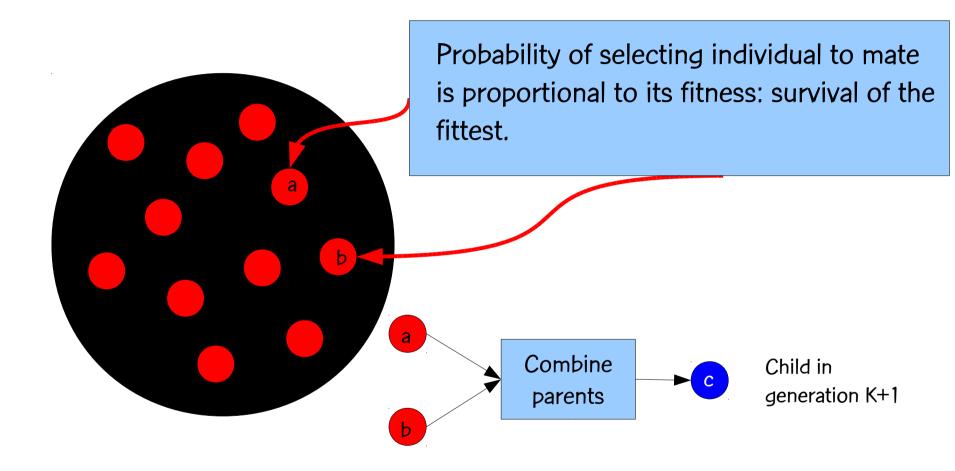

Individuals from one generation are combined to produce offspring that make up next generation.

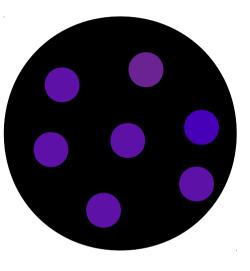

Probability of selecting individual to mate is proportional to its fitness: survival of the fittest.

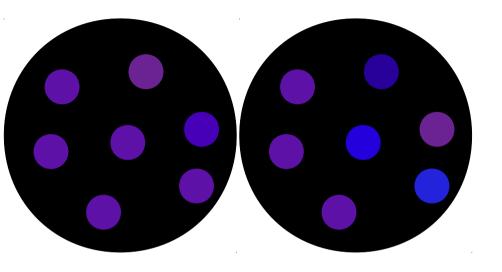

Parents drawn from generation K

If every random-key array corresponds to a feasible solution: Mating always produces feasible offspring.

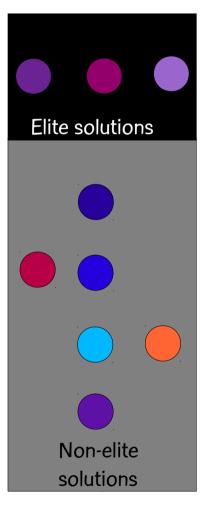

Initial population is made up of P random-key vectors, each with N keys, each having a value generated uniformly at random in the interval (0,1].

At the K-th generation, compute the cost of each solution ...

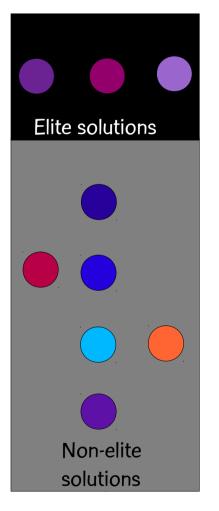

Population K

At the K-th generation, compute the cost of each solution and partition the solutions into two sets:

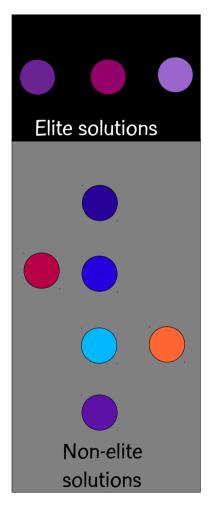

Population K

At the K-th generation, compute the cost of each solution and partition the solutions into two sets: elite solutions and non-elite solutions.

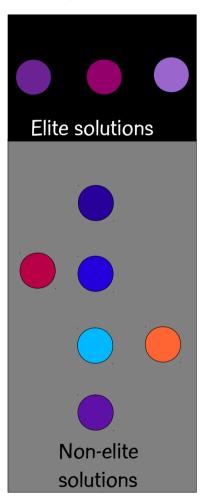

Population K

At the K-th generation, compute the cost of each solution and partition the solutions into two sets: elite solutions and non-elite solutions. Elite set should be smaller of the two sets and contain best solutions.

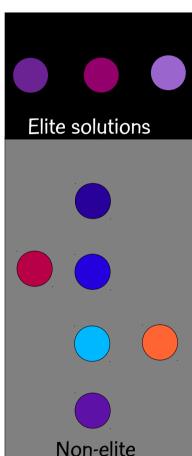

Population K

**Evolutionary dynamics** 

Population K

   K to population K+1
- Add R random solutions (mutants)
   to population K+1
- While K+1-th population < P</li>
  - RANDOM-KEY GA: Use any two solutions in population K to produce child in population K+1. Mates are chosen at random.

# Biased random key GA

BRKGA: Probability child inherits key of elite

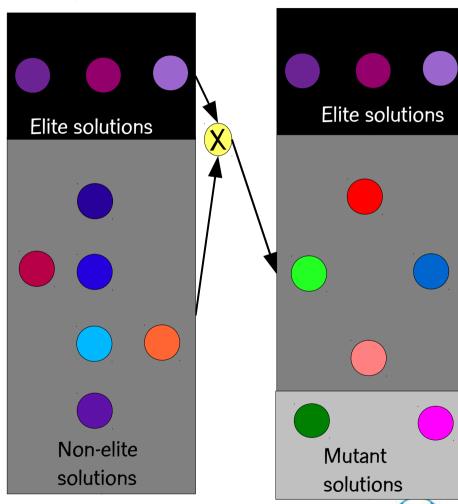

parent > 0.5

Population K

Population K+1

## **Evolutionary dynamics**

- Copy elite solutions from population
   K to population K+1
- Add R random solutions (mutants)
   to population K+1
- While K+1-th population < P</li>
  - RANDOM-KEY GA: Use any two solutions in population K to produce child in population K+1. Mates are chosen at random.
  - BIASED RANDOM-KEY GA: Mate elite solution with non-elite of population K to produce child in population K+1.
     Mates are chosen at random.

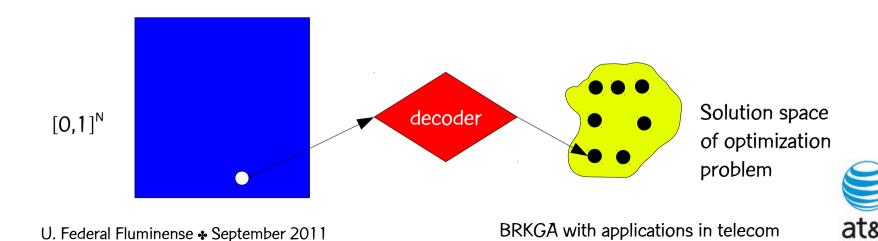

## **Observations**

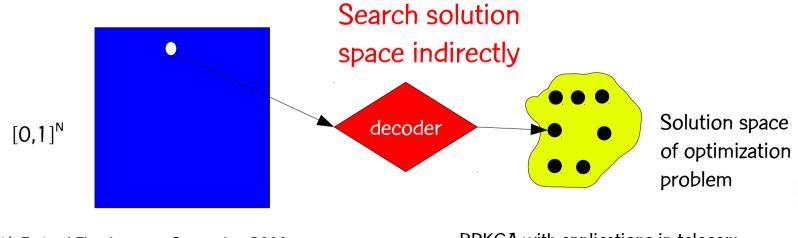

- Random method: keys are randomly generated so solutions are always random vectors
- Elitist strategy: best solutions are passed without change from one generation to the next
- Child inherits more characteristics of elite parent: one parent is always selected (with replacement) from the small elite set and probability that child inherits key of elite parent > 0.5
- No mutation in crossover: mutants are used instead

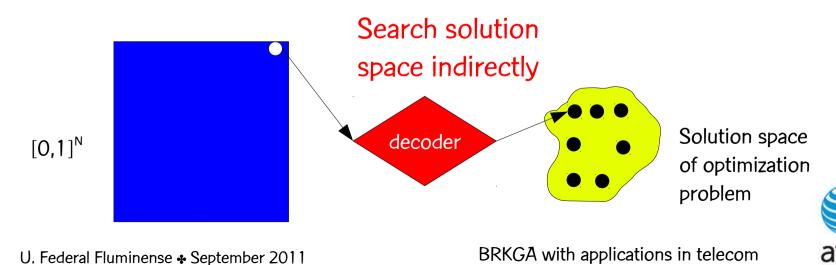

- A decoder is a deterministic algorithm that takes as input a random-key vector and returns a feasible solution of the optimization problem and its cost.
- Bean (1994) proposed decoders based on sorting the random-key vector to produce a sequence.
- A random-key GA searches the solution space indirectly by searching the space of random keys and using the decoder to evaluate fitness of the random key.

### Framework for biased random-key genetic algorithms

### Framework for biased random-key genetic algorithms

## Framework for biased random-key genetic algorithms

- Encoding is always done the same way, i.e. with a vector of N random-keys (parameter N must be specified)
- Decoder that takes as input a vector of N random-keys and outputs the corresponding solution of the combinatorial optimization problem and its cost (this is usually a heuristic)

- Size of population
- Size of elite partition
- Size of mutant set
- Child inheritance probability
- Stopping criterion

- Encoding is always done the same way, i.e. with a vector of N random-keys (parameter N must be specified)
- Decoder that takes as input a vector of N random-keys and outputs the corresponding solution of the combinatorial optimization problem and its cost (this is usually a heuristic)

- Size of population: a function of N, say N or 2N
- Size of elite partition
- Size of mutant set
- Child inheritance probability
- Stopping criterion

- Encoding is always done the same way, i.e. with a vector of N random-keys (parameter N must be specified)
- Decoder that takes as input a vector of N random-keys and outputs the corresponding solution of the combinatorial optimization problem and its cost (this is usually a heuristic)

- Size of population: a function of N, say N or 2N
- Size of elite partition: 15-25% of population
- Size of mutant set
- Child inheritance probability
- Stopping criterion

- Encoding is always done the same way, i.e. with a vector of N random-keys (parameter N must be specified)
- Decoder that takes as input a vector of N random-keys and outputs the corresponding solution of the combinatorial optimization problem and its cost (this is usually a heuristic)

- Size of population: a function of N, say N or 2N
- Size of elite partition: 15-25% of population
- Size of mutant set: 5-15% of population
- Child inheritance probability
- Stopping criterion

- Encoding is always done the same way, i.e. with a vector of N random-keys (parameter N must be specified)
- Decoder that takes as input a vector of N random-keys and outputs the corresponding solution of the combinatorial optimization problem and its cost (this is usually a heuristic)

- Size of population: a function of N, say N or 2N
- Size of elite partition: 15-25% of population
- Size of mutant set: 5-15% of population
- Child inheritance probability: > 0.5, say 0.7
- Stopping criterion

- Decoder that takes as input a vector of N random-keys and outputs the corresponding solution of the combinatorial optimization problem and its cost (this is usually a heuristic)

- Size of population: a function of N, say N or 2N
- Size of elite partition: 15-25% of population
- Size of mutant set: 5-15% of population
- Child inheritance probability: > 0.5, say 0.7
- Stopping criterion: e.g. time, # generations, solution quality,# generations without improvement

# Applications in telecommunications

## Applications in telecommunications

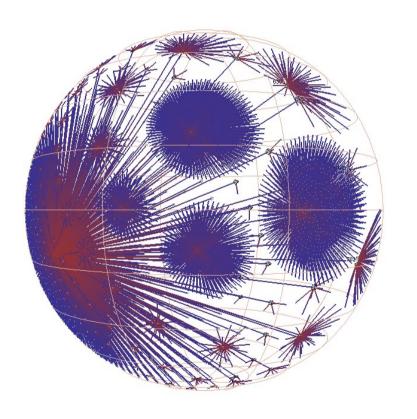

- Routing in IP networks
- Design of survivable IP networks
- Redundant server location for content distribution
- Regenerator location
- Routing and wavelength assignment in optical networks

# OSPF routing in IP networks

## The Internet

- The Internet is composed of many (inter-connected) autonomous systems (AS).
- An AS is a network controlled by a single entity, e.g. ISP, university, corporation, country, ...

Global AS-level Map

# Routing

- A packet is sent from a origination router S to a destination router T.
- S and T may be in
  - same AS:
  - different ASes:

# Routing

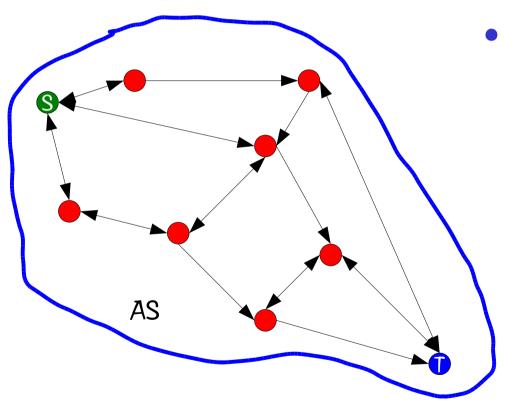

- A packet is sent from a origination router S to a destination router T.
- S and T may be in
  - same AS: IGP routing
  - different ASes:

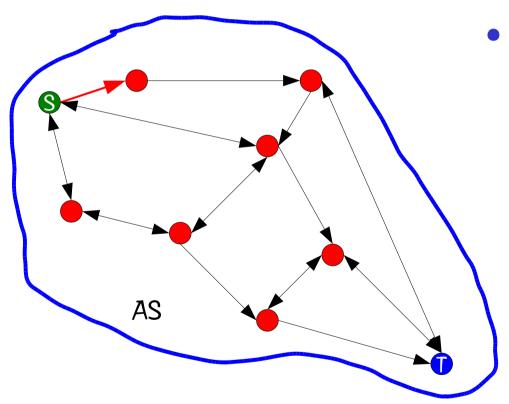

# Routing

- A packet is sent from a origination router S to a destination router T.
- S and T may be in
  - same AS: IGP routing
  - different ASes: BGP routing

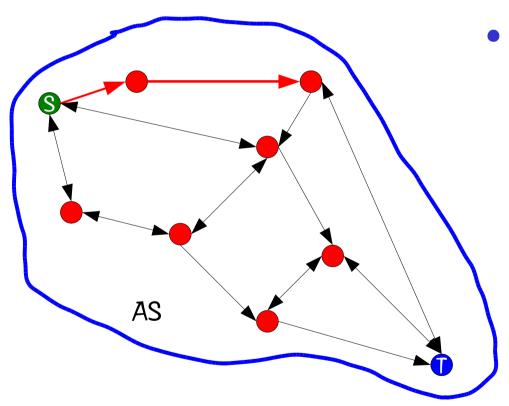

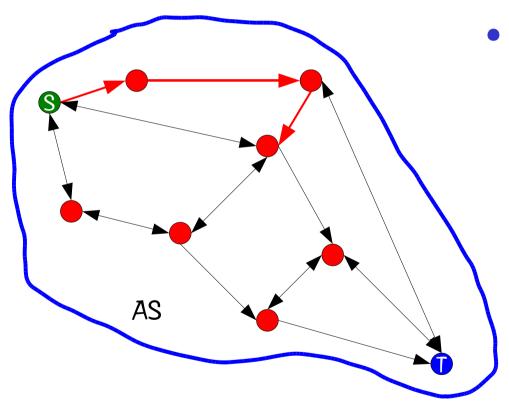

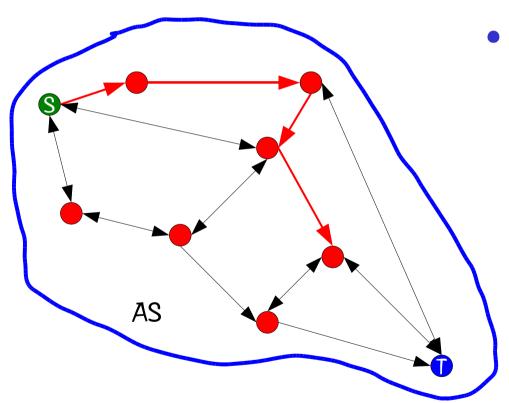

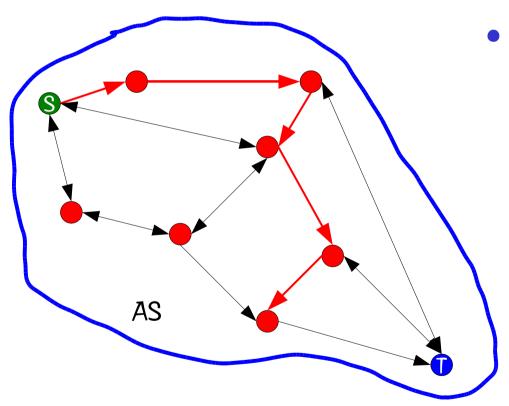

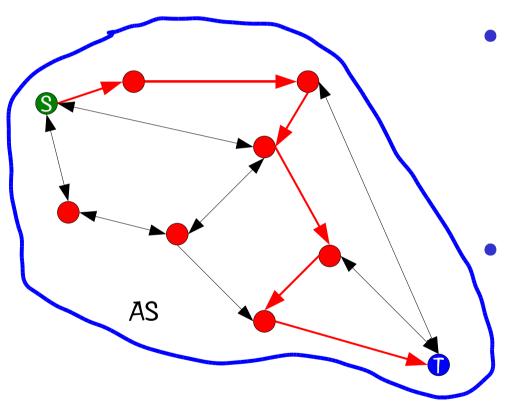

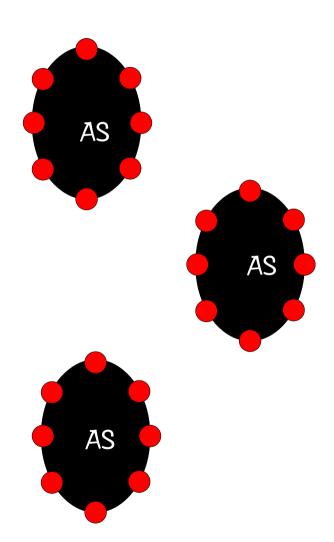

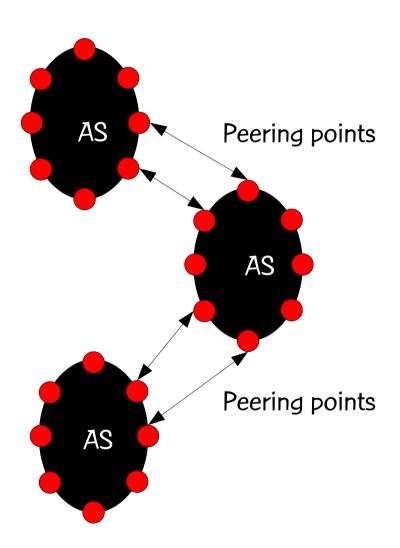

- IGP (interior gateway protocol) routing is concerned with routing within an AS.
- Routing decisions are made by AS operator.

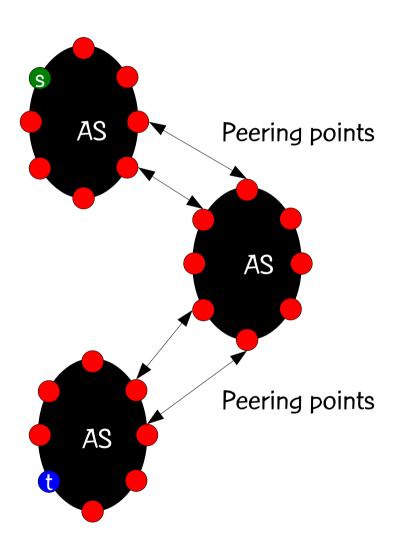

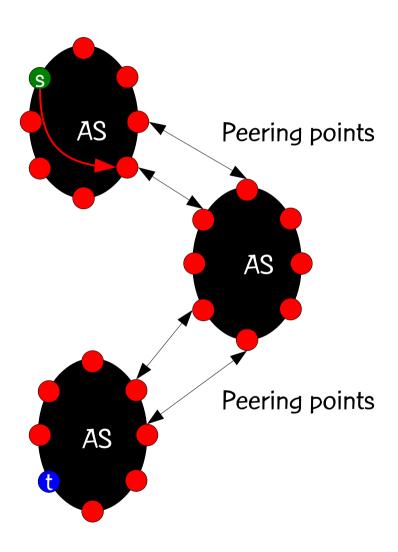

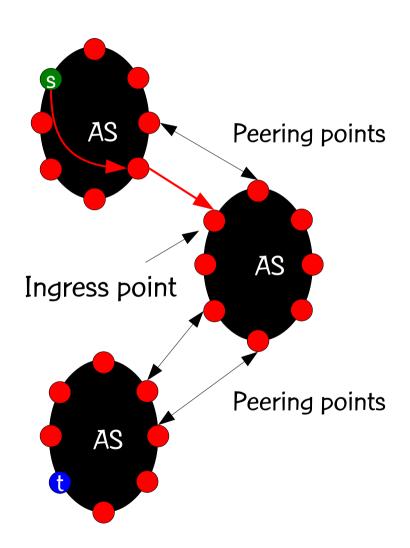

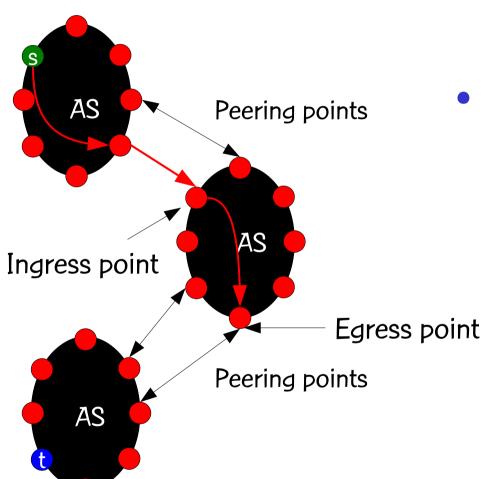

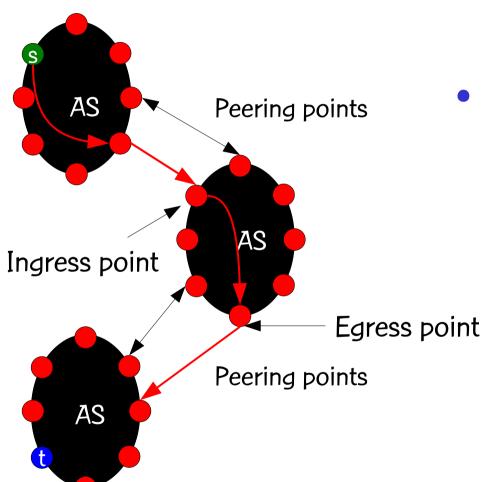

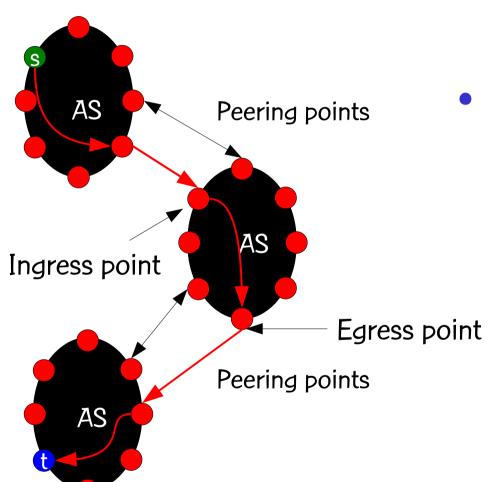

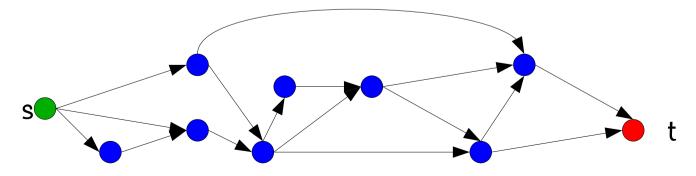

• Given a network G = (N,A), where N is the set of routers and A is the set of links.

- Given a network G = (N,A), where N is the set of routers and A is the set of links.
- The OSPF (open shortest path first) routing protocol assumes each link a has a weight w(a) assigned to it so that a packet from a source router s to a destination router t is routed on a shortest weight path from s to t.

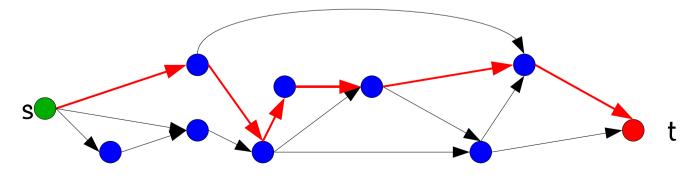

- Given a network G = (N,A), where N is the set of routers and A is the set of links.
- The OSPF (open shortest path first) routing protocol assumes each link a has a weight w(a) assigned to it so that a packet from a source router s to a destination router t is routed on a shortest weight path from s to t.

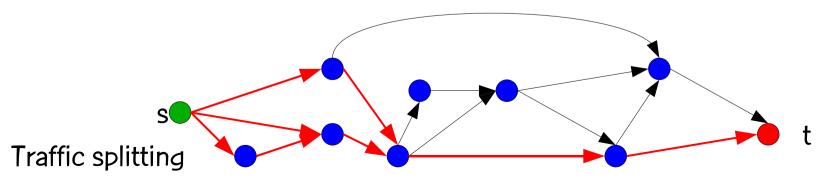

- Given a network G = (N,A), where N is the set of routers and A is the set of links.
- The OSPF (open shortest path first) routing protocol assumes each link a has a weight w(a) assigned to it so that a packet from a source router s to a destination router t is routed on a shortest weight path from s to t.

- Given a network G = (N,A), where N is the set of routers and A is the set of links.
- The OSPF (open shortest path first) routing protocol assumes each link a has a weight w(a) assigned to it so that a packet from a source router s to a destination router t is routed on a shortest weight path from s to t.

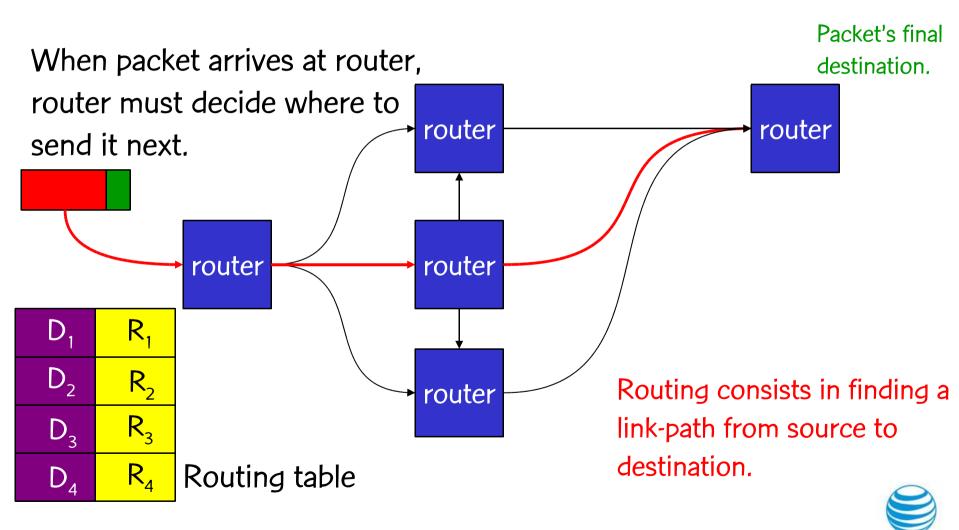

- By setting OSPF weights appropriately, one can do traffic engineering, i.e. route traffic so as to optimize some objective (e.g. minimize congestion, maximize throughput, etc.).
  - Some recent papers on this topic:
    - Fortz & Thorup (2000, 2004)
    - Ramakrishnan & Rodrigues (2001)
    - Sridharan, Guérin, & Diot (2002)
    - Fortz, Rexford, & Thorup (2002)
    - Ericsson, Resende, & Pardalos (2002)
    - Buriol, Resende, Ribeiro, & Thorup (2002, 2005)
    - Reis, Ritt, Buriol, & Resende (2011)

- By setting OSPF weights appropriately, one can do traffic engineering, i.e. route traffic so as to optimize some objective (e.g. minimize congestion, maximize throughput, etc.).

## Packet routing

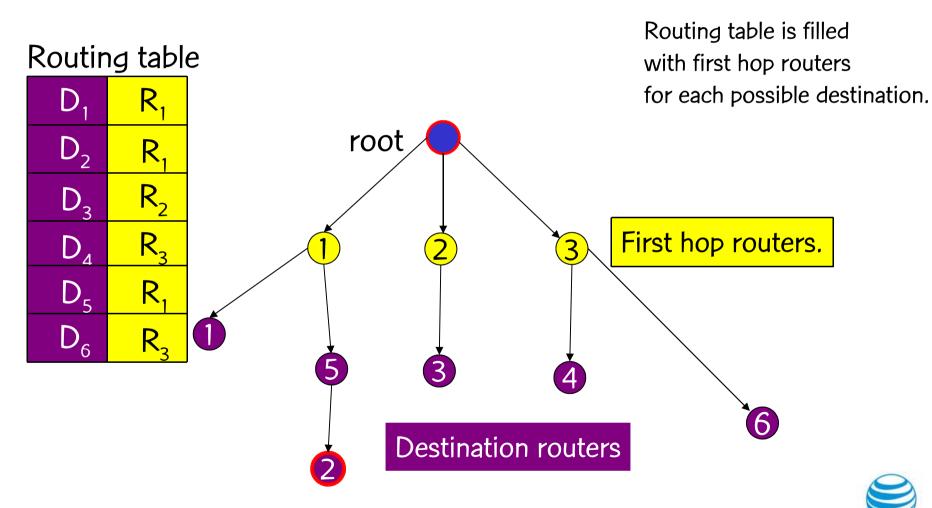

- Assign an integer weight  $\in [1, w_{max}]$  to each link in AS. In general,  $w_{max} = 65535 = 2^{16} 1$ .
- Each router computes tree of shortest weight paths to all other routers in the AS, with itself as the root, using Dijkstra's algorithm.

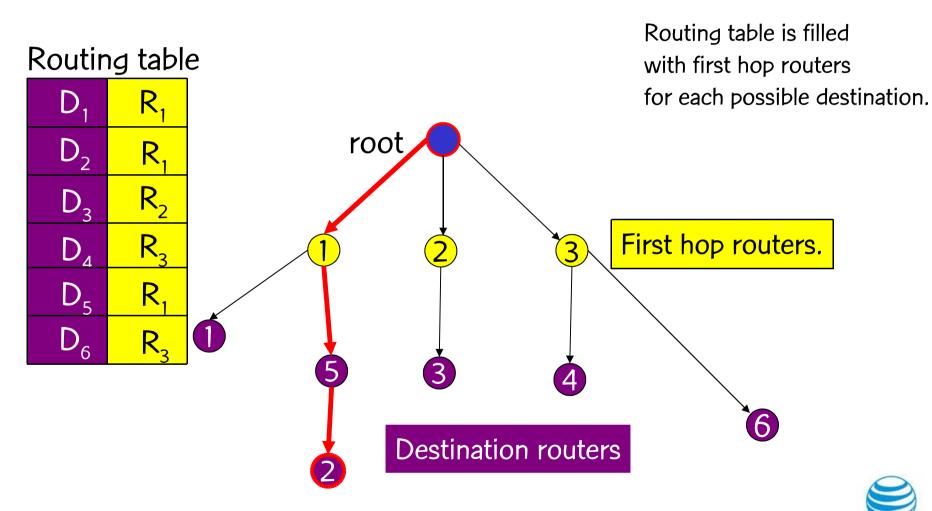

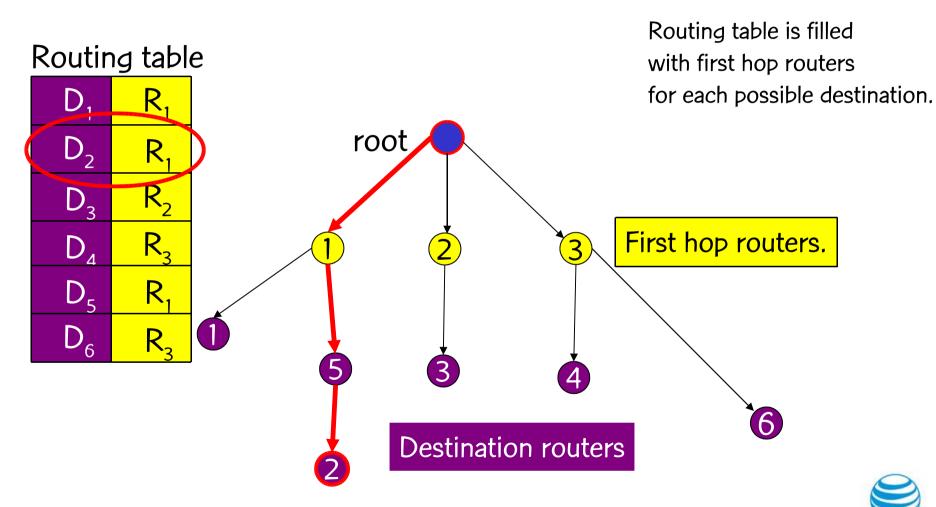

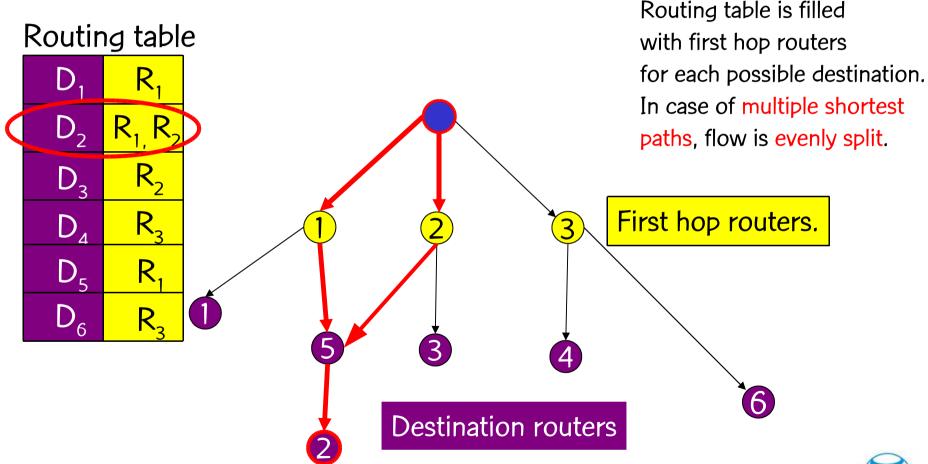

## OSPF weight setting

- OSPF weights are assigned by network operator.
  - CISCO assigns, by default, a weight proportional to the inverse of the link bandwidth (Inv Cap).
  - If all weights are unit, the weight of a path is the number of hops in the path.
- We propose two BRKGA to find good OSPF weights.

#### Minimization of congestion

- Consider the directed capacitated network G = (N,A,c), where N are routers, A are links, and  $c_a$  is the capacity of link  $a \in A$ .
- We use the measure of Fortz & Thorup (2000) to compute congestion:

$$\Phi = \Phi_1(//) + \Phi_2(//) + ... + \Phi_{|A|}(////)$$

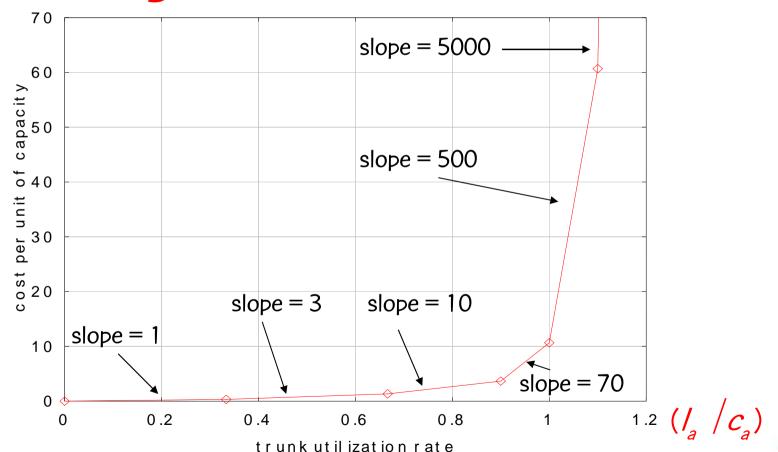

where  $l_a$  is the load on link  $a \in A$ ,

 $\Phi_{a}(\slash_a)$  is piecewise linear and convex,

$$\Phi_a(0) = 0$$
, for all  $a \in A$ .

# Piecewise linear and convex $\Phi_a(\slash_a)$ link congestion measure

#### OSPF weight setting problem

- Given a directed network G = (N, A) with link capacities  $c_a \in A$  and demand matrix  $D = (d_{s,t})$  specifying a demand to be sent from node s to node t:
  - Assign weights  $w_a \in [1, w_{max}]$  to each link  $a \in A$ , such that the objective function  $\Phi$  is minimized when demand is routed according to the OSPF protocol.

M. Ericsson, M.G.C.R., & P.M. Pardalos, "A genetic algorithm for the weight setting problem in OSPF routing," J. of Combinatorial Optimization, vol. 6, pp. 299–333, 2002.

   should be installed on each arc
   a ∈ A,
- such that all the demand can be routed on the network even when any single arc fails.

Buriol, R., & Thorup (Networks, 2007)

#### Given

- directed graph G = (N,A), where
   N is the set of routers, A is the
   set of potential arcs where
   capacity can be installed,
- a demand matrix D that for each pair (s,t) ∈ N×N, specifies the demand D(s,t) between s and t,
- a cost K(a) to lay fiber on arc a
- a capacity increment C for the fiber.

- OSPF weight w(a) to assign to each arc  $a \in A$ ,
- which arcs should be used to deploy fiber and how many units (multiplicities) M(a) of capacity C should be installed on each arc a ∈ A,
- such that all the demand can be routed on the network even when any single arc fails.
- Min total design cost =  $\sum_{a \in A} M(a) \times K(a)$ .

Tech report version:

http://www2.research.att.com/~mgcr/doc/monitoring-alenex.pdf

 Suppose a number of users located at nodes in a network demand content.

- Suppose a number of users located at nodes in a network demand content.
- Copies of content are stored throughout the network in data warehouses.

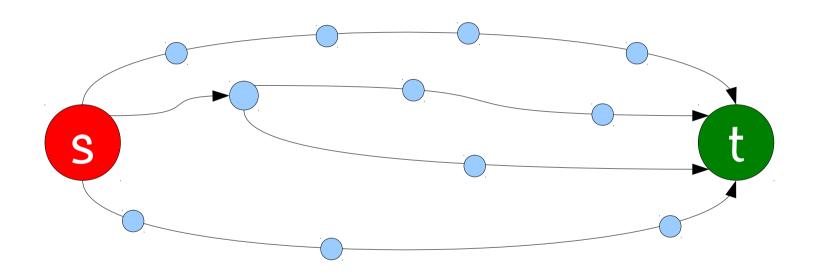

- Suppose a number of users located at nodes in a network demand content.
- Copies of content are stored throughout the network in data warehouses.
- Content is sent from data warehouse to user on routes determined by OSPF.

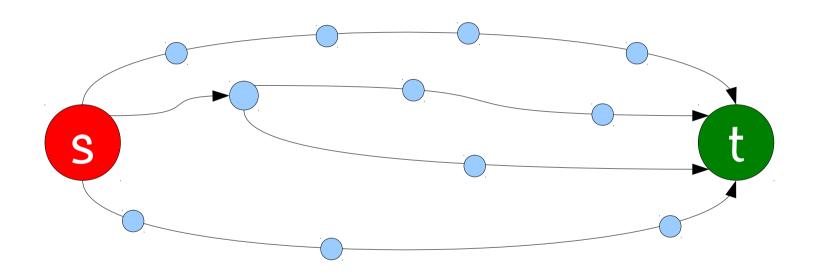

- Suppose a number of users located at nodes in a network demand content.
- Copies of content are stored throughout the network in data warehouses.
- Content is sent from data warehouse to user on routes determined by OSPF.
- Problem: Locate minimum number of warehouses in network such all users get their content even in presence of edge failures.

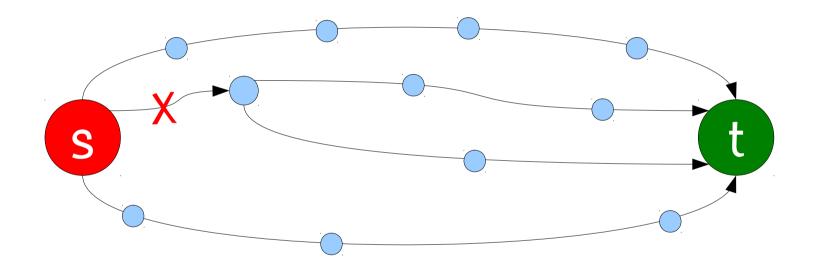

Traffic from node s to node t flows on paths defined by OSPF.

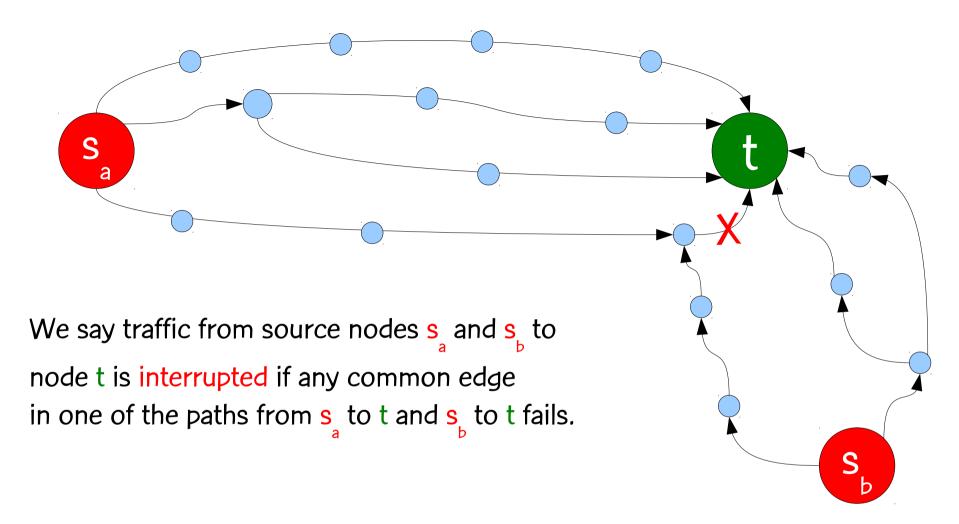

We don't know on which path a particular packet will flow.

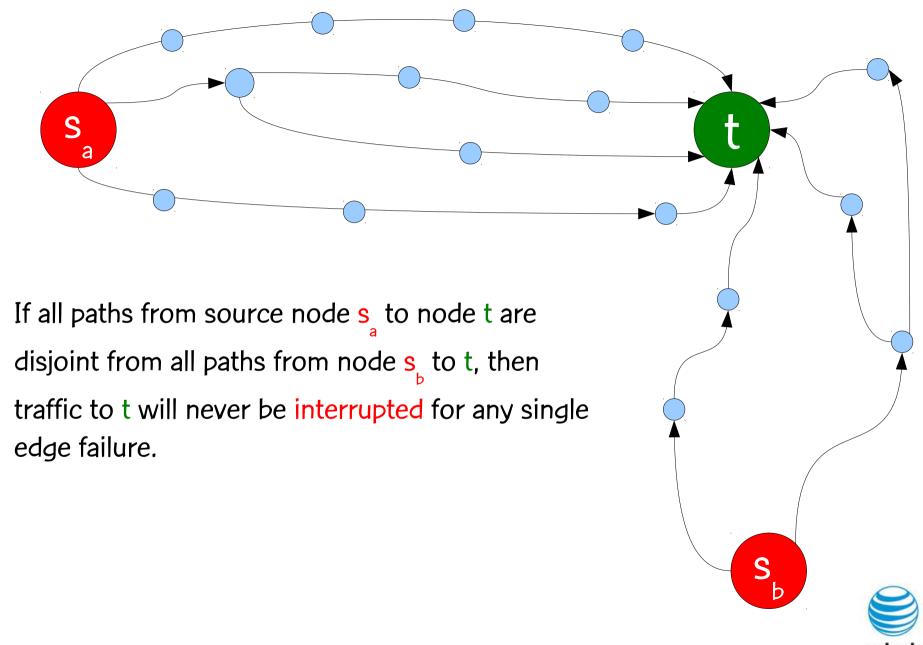

We say traffic from node s to node t is interrupted if any edge in one of the paths from s to t fails.

Suppose nodes  $b_1$ ,  $b_2$ , ... want some content (e.g. video).

We want the smallest set **S** of servers such that:

for every  $b_i$  there exist  $m_1$ ,  $m_2 \in \mathbf{S}$  both of which can provide content to  $b_i$ 

 $b_2$   $b_3$   $m_4$ 

Suppose nodes  $b_1$ ,  $b_2$ , ... want some content (e.g. video).

We want the smallest set **S** of servers such that:

for every  $b_i$  there exist  $m_1$ ,  $m_2 \in \mathbf{S}$  both of which can provide content to  $b_i$ 

Suppose nodes  $b_1$ ,  $b_2$ , ... want some content (e.g. video).

We want the smallest set **S** of servers such that:

for every  $b_i$  there exist  $m_1$ ,  $m_2 \in \mathbf{S}$  both of which can provide content to  $b_i$ 

Suppose nodes  $b_1$ ,  $b_2$ , ... want some content (e.g. video).

We want the smallest set **S** of servers such that:

for every  $b_i$  there exist  $m_1$ ,  $m_2 \in \mathbf{S}$  both of which can provide content to  $b_i$ 

Suppose nodes  $b_1$ ,  $b_2$ , ... want some content (e.g. video).

We want the smallest set **S** of servers such that:

for every  $b_i$  there exist  $m_1$ ,  $m_2 \in \mathbf{S}$  both of which can provide content to  $b_i$ 

 $\frac{1}{b_2}$ 

#### • Given:

- A directed network G = (V, E);
- A set of nodes  $B \subseteq E$  where content-demanding users are located;
- A set of nodes M ⊆ E where content warehouses can be located;
- The set of all OSPF paths from m to b, for m ∈ M and  $b \in B$ .

#### Compute:

- The set of triples {  $m_1$ ,  $m_2$ , b }', i = 1, 2, ..., T, such that all paths from  $m_1$  to b and from  $m_2$  to b are disjoint, where  $m_1$ ,  $m_2 ∈ M$  and b ∈ B.
- Note that if  $B \cap M \neq \emptyset$ , then some triples will be of the type  $\{b, b, b, b\}$ , where  $b \in B \cap M$ , i.e. a data warehouse that is co-located with a user can provide content to the user by itself.

- Solve the covering by pairs problem:
  - Find a smallest-cardinality set M\*⊆ M such that for all b∈ B, there exists a triple { m₁, m₂, b } in the set of triples such that m₁, m₂∈ M\*.

• initialize partial cover M\* = { }

- initialize partial cover M\* = { }
- while M\* is not a cover do:

- initialize partial cover M\* = { }
- while M\* is not a cover do:
  - find m ∈ M \ M\* such that M\*  $\cup$  {m} covers a maximum number of additional user nodes (break ties by vertex index) and set M\* = M\*  $\cup$  {m}

- initialize partial cover M\* = { }
- while M\* is not a cover do:
  - find m ∈ M \ M\* such that M\*  $\cup$  {m} covers a maximum number of additional user nodes (break ties by vertex index) and set M\* = M\*  $\cup$  {m}
  - if no m ∈ M \ M\* yields an increase in coverage, then choose a pair  $\{m_1, m_2\}$  ∈ M \ M\* that yields a maximum increase in coverage and set M\* = M\*  $\cup$   $\{m_1\}$   $\cup$   $\{m_2\}$

- initialize partial cover M\* = { }
- while M\* is not a cover do:
  - find m ∈ M \ M\* such that M\*  $\cup$  {m} covers a maximum number of additional user nodes (break ties by vertex index) and set M\* = M\*  $\cup$  {m}
  - if no  $m \in M \setminus M^*$  yields an increase in coverage, then choose a pair  $\{m_1, m_2\} \in M \setminus M^*$  that yields a maximum increase in coverage and set  $M^* = M^* \cup \{m_1\} \cup \{m_2\}$
  - if no pair exists, then the problem is infeasible

# BRKGA for redundant content distribution

#### Encoding:

 Telecommunication systems use optical signals to transmit information

- Telecommunication systems use optical signals to transmit information
- Strength of signal deteriorates and loses power as it gets farther from source

- Telecommunication systems use optical signals to transmit information
- Strength of signal deteriorates and loses power as it gets farther from source
- Signal must be regenerated periodically to reach destination: Regenerators

- Telecommunication systems use optical signals to transmit information
- Strength of signal deteriorates and loses power as it gets farther from source
- Signal must be regenerated periodically to reach destination: Regenerators
- Regenerators are expensive: minimize the number of regenerators in the network

#### Given:

- Graph G=(V,E), where V are vertices, E are edges, where edge (i,j) has a real-valued length d(i,j) > 0
- D is the maximum length that a signal can travel before it must regenerated

#### • Find:

- Paths that connect all pairs of nodes in V×V
- Nodes where it is necessary to locate single regenerators
- Minimize number of deployed regenerators

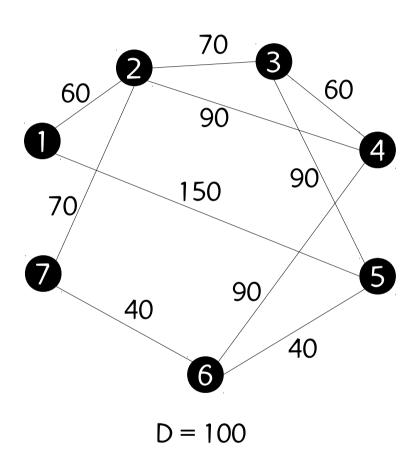

- Path between {s,t} ∈ E
  - { (s,v[1]), (v[1],v[2]), ...,(v[k],t) } is formed by one or more path segments
- Path segment is sequence of consecutive edges
  - { (v[i],v[i+1]), (v[i+1],v[i+2]), ...,(v[q-1],v[q]) } in the path satisfying the condition

 $d(v[i],v[i+1]) + d(v[i+1],v[i+2]) + \cdots + (v[q-1],v[q]) \le D$ 

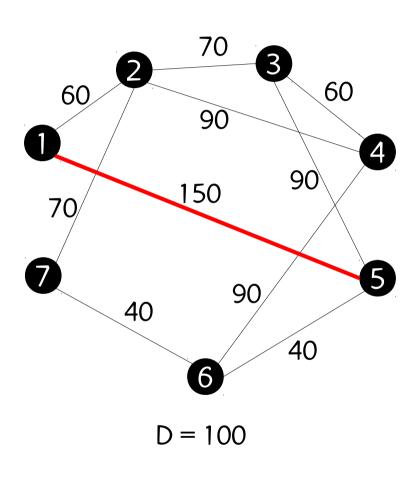

- If total length of path is no more than D, then path consists of a single path segment
- Otherwise, it consists of one or more segments
  - Regenerators will be located in the internal nodes of the path

7-node graph with D = 100

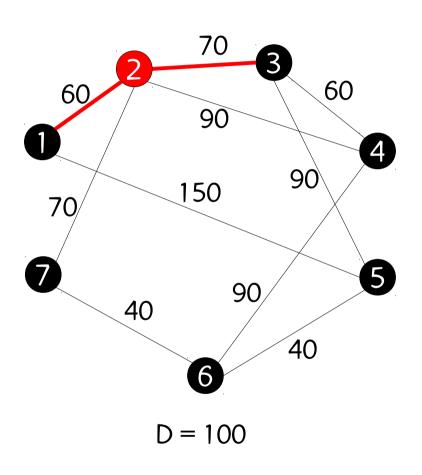

#### (1) Note that:

- -D(1,5) = 150 > 100 = D
- Edge (1,5) cannot be part of any path

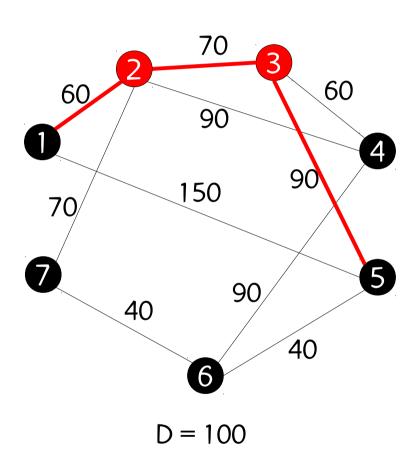

#### (2) Note that:

 Shortest path from 1 to 3 is  $\{(1,2),(2,3)\}$  with total length 60 + 70 = 130 > 100 = D

$$60 + 70 = 130 > 100 = D$$

 Must be decomposed into two path segments { (1,2) } and {(2,3)} with a regenerator in node 2

#### (3) Note that:

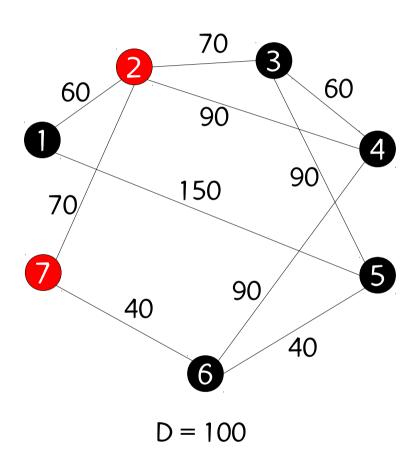

- Shortest feasible path from 1 to 5 is { (1,2), (2,3), (3,5) } with total length
  60 + 70 + 90 = 220 >
  100 = D
- Must be decomposed into three path segments { (1,2) },
  { (2,3) }, and { (3,5) } with regenerators in nodes 2 and 3

#### (4) Note that:

- Shortest feasible path from 5 to 7 is  $\{ (5,6), (6,7) \}$  with total length  $40 + 40 = 80 \le 100 = D$
- No regenerator is needed to connect nodes 5 and 7

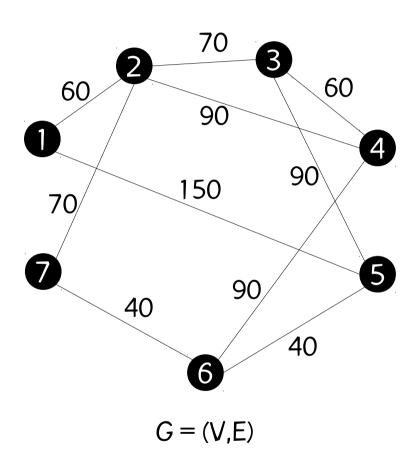

#### (5) Note that:

 Placing regenerator in nodes 2 and 7 allows for communication between all pairs of nodes in the graph

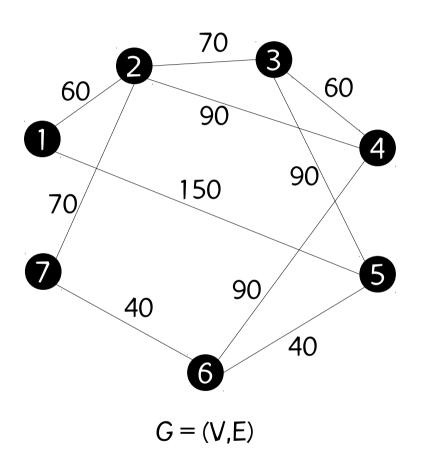

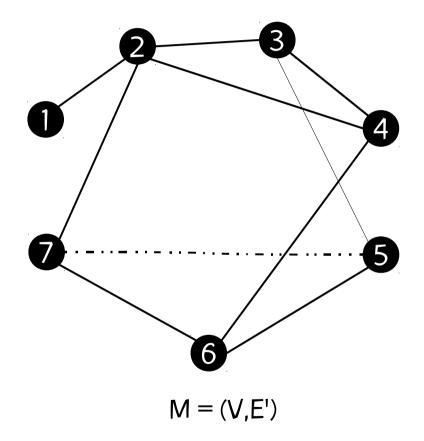

#### Given weighted graph G

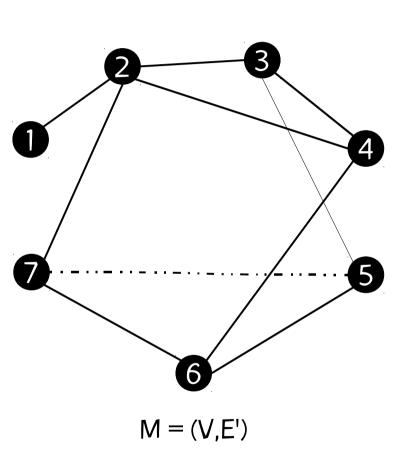

- Delete all edges having length greater than D
- For all non-adjacent nodes,
   add an edge between them
   of length equal to the
   corresponding shortest path
   in G if it is less than D
- Disregard all length info

 If M is complete, then there is no need for regenerators

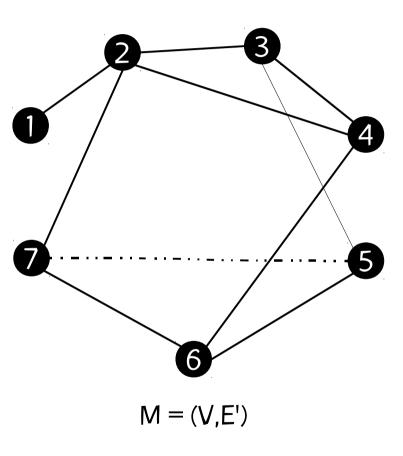

- If M is complete, then there is no need for regenerators
- If M is not connected, then the problem is infeasible

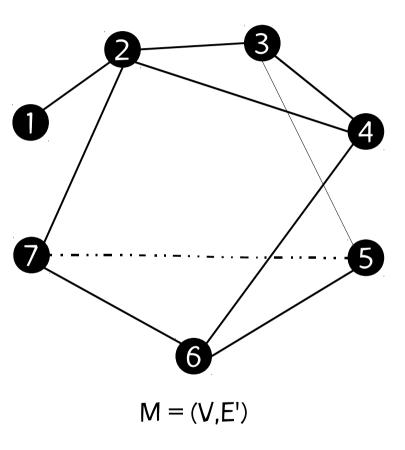

- If M is complete, then there is no need for regenerators
- If M is not connected, then the problem is infeasible
- Otherwise, one or more regenerators are needed

U. Federal Fluminense & September 2011

Scan V in order implied by Y

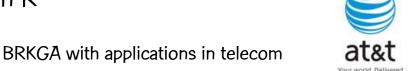

while come pair in  $V \times V$  cannot communicate (M = (V, E') is not complete):

Add next vertex v in order into R

Compute set X of pairs that do not communicate that would if v becomes a regenerator

Add X to E'

end while local search return R

# Routing and wavelength assignment in optical networks

 Objective: Route a set of connections (called lightpaths) and assign a wavelength to each of them.

- Objective: Route a set of connections (called lightpaths) and assign a wavelength to each of them.
- Two lightpaths may use the same wavelength, provided they do not share any common link.

- Objective: Route a set of connections (called lightpaths) and assign a wavelength to each of them.
- Two lightpaths may use the same wavelength, provided they do not share any common link.
- Connections whose paths share a common link in the network are assigned to different wavelengths (wavelength clash constraint).

- Objective: Route a set of connections (called lightpaths) and assign a wavelength to each of them.
- Two lightpaths may use the same wavelength, provided they do not share any common link.
- Connections whose paths share a common link in the network are assigned to different wavelengths (wavelength clash constraint).
- If no wavelength converters are available, the same wavelength must be assigned along the entire route (wavelength continuity constraint).

 Variants of RWA are characterized by different optimization criteria, traffic patterns, and whether wavelength conversion is available or not.

- Variants of RWA are characterized by different optimization criteria, traffic patterns, and whether wavelength conversion is available or not.
- We consider the min-RWA offline variant:

- Variants of RWA are characterized by different optimization criteria, traffic patterns, and whether wavelength conversion is available or not.
- We consider the min-RWA offline variant:
  - Connection requirements are known beforehand.

- Variants of RWA are characterized by different optimization criteria, traffic patterns, and whether wavelength conversion is available or not.
- We consider the min-RWA offline variant:
  - Connection requirements are known beforehand.
  - No wavelength conversion is possible.

- Variants of RWA are characterized by different optimization criteria, traffic patterns, and whether wavelength conversion is available or not.
- We consider the min-RWA offline variant:
  - Connection requirements are known beforehand.
  - No wavelength conversion is possible.
  - Objective is to minimize the number of wavelengths used for routing all connections.

- Variants of RWA are characterized by different optimization criteria, traffic patterns, and whether wavelength conversion is available or not.
- We consider the min-RWA offline variant:
  - Connection requirements are known beforehand.
  - No wavelength conversion is possible.
  - Objective is to minimize the number of wavelengths used for routing all connections.
  - Asymmetric traffic matrices and bidirectional links.

  - Asymmetric traffic matrices and bidirectional links.
  - NP-hard (Erlebach and Jansen, 2001)

### Connections

 $c \leftrightarrow m$ 

 $d \leftrightarrow b$ 

 $e \leftrightarrow h$ 

 $a \leftrightarrow e$ 

 $b \leftrightarrow f$ 

Connections:  $(a \leftrightarrow e) (b \leftrightarrow f) (c \leftrightarrow m) (d \leftrightarrow b) (e \leftrightarrow h)$ 

### Heuristic of N. Skorin-Kapov (EJOR, 2007)

- Associates the min-RWA with the bin packing problem.
  - Wavelengths are associated with bins.
  - The capacity of a bin is defined as its number of arcs.
  - The size of a connection is defined as the number of arcs in its shortest path.

### Heuristic of N. Skorin-Kapov (EJOR, 2007)

- Associates the min-RWA with the bin packing problem.
  - Wavelengths are associated with bins.
  - The capacity of a bin is defined as its number of arcs.
  - The size of a connection is defined as the number of arcs in its shortest path.
- Developed RWA heuristics based on the following classical bin packing heuristics:
  - First Fit (FF)
  - Best Fit (BF)
  - First Fit Decreasing (FFD)
  - Best Fit Decreasing (BFD)

### Heuristic of N. Skorin-Kapov (EJOR, 2007)

# **BFD-RWA**

### N. Skorin-Kapov (2007); Noronha, R., and Ribeiro (2008)

- Input:
  - A directed graph G representing the network topology.
  - A set T of connection requests.
  - The value d of of the maximum number of arcs in each route. It is set to be the maximum of the square root of the number of links in the network and the diameter of G.
- Starts with only one copy of G (called G<sub>1</sub>).
- Connections are selected according to non-increasing order of the lengths of their shortest paths in  $G_i$ . Ties are broken at random.
- The connection is assigned wavelength i, and the arcs along path are deleted from  $G_i$ .
- If no existing bin can accommodate the connection with fewer than d arcs, a new bin is created.

### BRKGA for RWA: GA-RWA

T.F. Noronha, M.G.C.R., and C.C. Ribeiro, "A biased random-key genetic algorithm for routing and wavelength assignment," J. of Global Optimization, vol. 50, pp. 503–518, 2011.

Tech report version:

http://www.research.att.com/~mgcr/doc/garwa-full.pdf

#### BRKGA for RWA: GA-RWA

Noronha, R., and Ribeiro (2011)

 Encoding of solution: A vector X of |T| random keys in the range [0,1), where T is the set of connection request node pairs.

#### BRKGA for RWA: GA-RWA

Noronha, R., and Ribeiro (2011)

- Encoding of solution: A vector X of |T| random keys in the range [0,1), where T is the set of connection request node pairs.
- Decoding:
  - 1) Sort the connection in set T in non-increasing order of
     c(i) = SP(i) ×10 + X[i], for each connection i ∈ T.
  - 2) Apply BFD-RWA in the order determined in step 1.

#### BRKGA for RWA: GA-RWA

Noronha, R., and Ribeiro (2011)

- Encoding of solution: A vector X of |T| random keys in the range [0,1), where T is the set of connection request node pairs.
- Decoding:
  - 1) Sort the connection in set T in non-increasing order of
     c(i) = SP(i) ×10 + X[i], for each connection i ∈ T.
  - Apply BFD-RWA in the order determined in step 1.

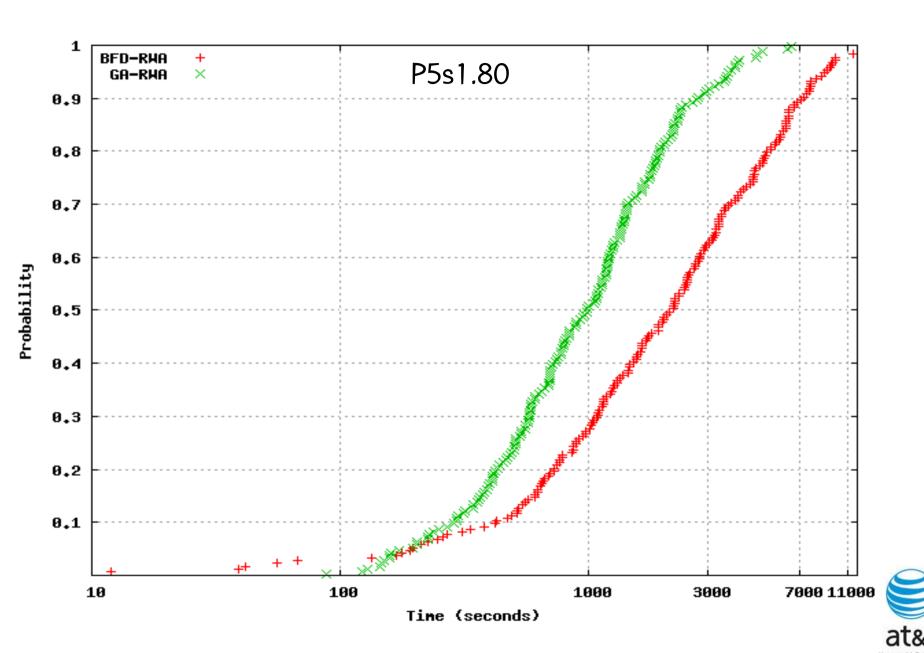

Since there are many ties connection pairs with The same SP(i) value, in the original algorithm of Skorin-Kapov, ties are broken at random. In the BRKGA, the algorithm "learns" how to break ties.

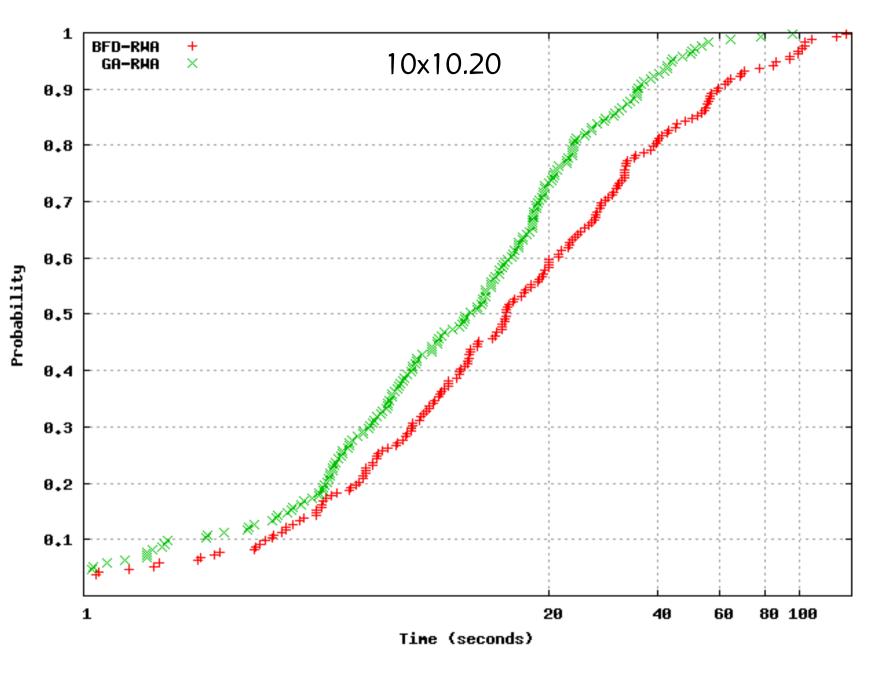

#### **Experiments**

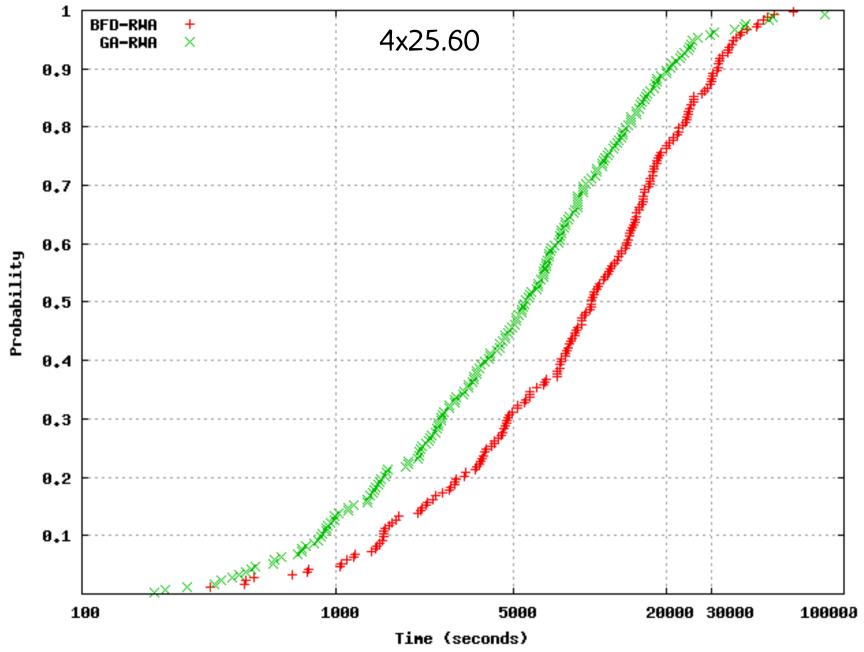

- Compare multi-start version of Skorin-Kapov's heuristic (MS-RWA) with GA-RWA.
- Make 200 independent runs of each heuristic of each heuristic on five instances, stopping when target solution was found (target was set to be best solution found by MS-RWA after 10,000 multi-start iterations.
- Plot CDF (runtime distribution) for each heuristic.

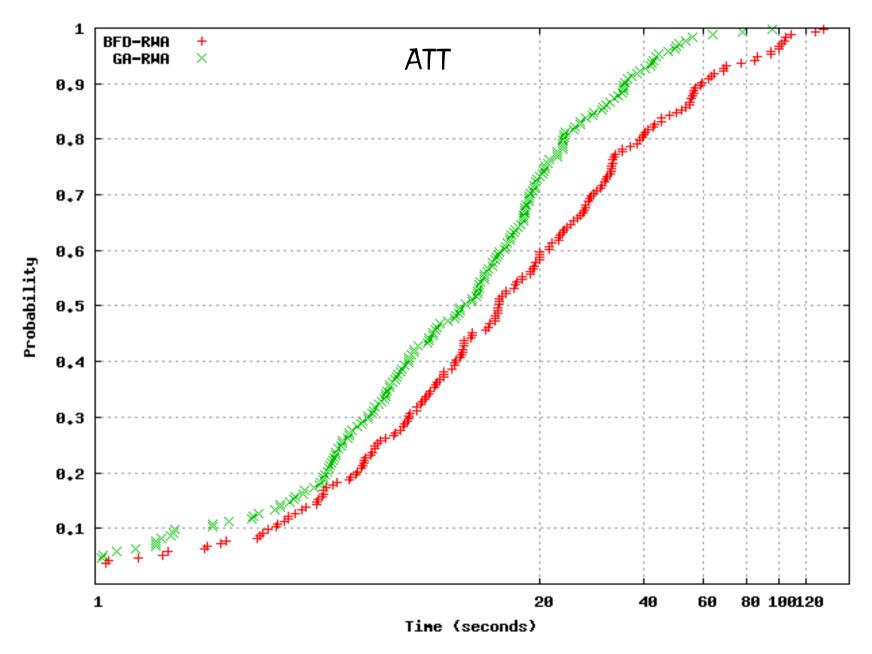

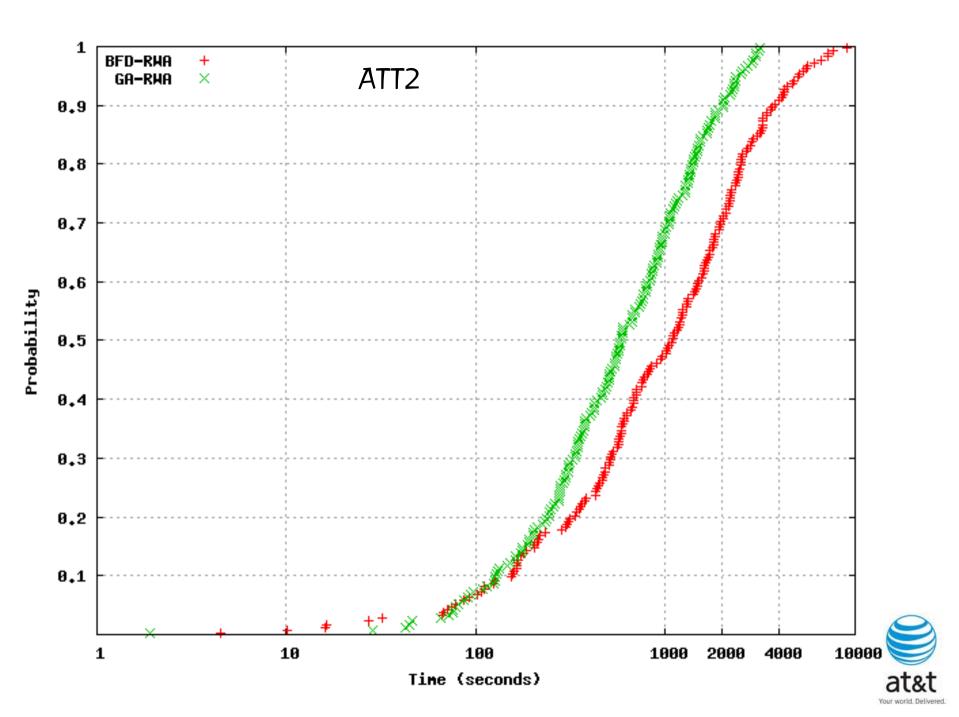

A small modification of Bean's RKGA results in a BRKGA.

- A small modification of Bean's RKGA results in a BRKGA.
- Though small, this modification, leads to significant performance improvements.

- A small modification of Bean's RKGA results in a BRKGA.
- Though small, this modification, leads to significant performance improvements.
- BRKGA are true metaheuristics: they coordinate simple heuristics and produce better solutions than the simple heuristics alone.
